

Product Suite Master Description

Product Suite Overview

The product suite is designed to make money usable across payments, stablecoin deployment, and institutional financial infrastructure.

Each product has a distinct role.

Pay by Bank is account-to-account payment infrastructure for businesses that want faster settlement, lower friction, and stronger operational control than traditional card-based payment flows. It is the direct payment rail in the suite.

Stablecoin Factory is the self-serve infrastructure product for teams that want to launch a simple stablecoin through a faster, lower-friction, AI-native deployment model. It is the entry point for simple issuance.

Digital Cash is enterprise infrastructure for already-licensed institutions that want to issue and operate their own digital cash programme with the full operational layer behind it, including settlement, treasury, ramps, and broader financial infrastructure capabilities. It is the institutional deployment layer in the suite.

Together, the suite is not a collection of disconnected offers. It is a focused product architecture built around one broader idea: making money more programmable, more operational, and easier to deploy across real commercial and financial environments.

Pay by Bank

Overview

Pay by Bank is UK account-to-account payment infrastructure for businesses that want a faster, lower-friction alternative to traditional card-based payment flows.

It is designed to help merchants move customers from payment initiation to completed settlement more directly, using open-banking rails rather than card rails. In practice, it gives merchants an instant bank-to-merchant payment flow that improves settlement speed, reduces payment friction, and creates stronger day-to-day operational control.

Pay by Bank should be understood as practical payment infrastructure rather than just another checkout option. It provides a cleaner route from initiated payment to completed settlement through a model that is easier to operate as volume grows.

Who it is for

Pay by Bank is built for UK merchants and payment-driven businesses that care about payment efficiency, settlement speed, operational control, and payment economics.

It is especially relevant for businesses where card fees, chargeback exposure, friction in the payment journey, or operational overhead have a direct impact on margin and performance. The initial commercial focus is on gaming, betting, trading, and other higher-risk or card-under-served verticals, with broader relevance over time for wallets, remittance, and e-commerce businesses where payment performance is commercially significant.

How it is sold

Pay by Bank is sold as direct payment infrastructure for businesses that want a better way to get paid.

The commercial message is not that it offers another payment method for the sake of variety. The message is that it gives merchants a more efficient payment rail with lower friction, faster settlement, and stronger control over how money moves into the business. It is positioned as a commercially usable product now in the UK, with future European expansion dependent on licensing rather than engineering.

Why it matters

Traditional card-based payment flows often come with unnecessary friction, higher costs, slower settlement, and operational complexity that compounds over time.

Pay by Bank matters because it offers a more direct route from customer bank account to merchant. It improves the economics and usability of payments for organisations that need stronger performance from their payment infrastructure and a more reliable operating model as transaction volume grows.

Core value

The core value of Pay by Bank is operationally efficient payment flow.

It gives businesses a direct bank payment rail with lower friction, faster settlement, and a stronger foundation for managing payment operations in practice. It is particularly valuable

where businesses are poorly served by card economics or exposed to unnecessary operational friction.

Short description

Pay by Bank is UK account-to-account payment infrastructure for businesses that want lower payment friction, faster settlement, and stronger operational control than traditional card-based flows.

Stablecoin Factory

Overview

Stablecoin Factory is an AI-native self-serve infrastructure product for launching a simple stablecoin through a low-friction deployment flow.

It is designed for teams that want a quicker route from idea to simple issuance without starting with the full complexity of enterprise deployment. It provides a structured way to deploy a simple stablecoin, start using the infrastructure in practice, and move from concept to live setup with less friction.

Stablecoin Factory should be understood as the simple deployment layer in the suite. It is for getting a stablecoin live through a more accessible, self-serve, AI-native experience, rather than for running the full institutional operating model.

Who it is for

Stablecoin Factory is built for builders, technical teams, innovation teams, product teams, and exploratory operators that want a straightforward way to deploy and test a simple stablecoin.

It is especially relevant where speed, experimentation, and self-serve deployment matter more than full institutional operating depth from day one. It is for teams that want to move from concept to live issuance through a clearer and more usable infrastructure route.

How it is sold

Stablecoin Factory is sold as an AI-native self-serve product.

The commercial message is that launching a simple stablecoin should not require a long enterprise process or a full custom infrastructure build from the start. It should be possible to deploy quickly, learn through real use, and move toward a broader operating model only when the use case requires it.

Why it matters

Many teams can see a stablecoin use case, but the path from concept to simple live deployment is still too heavy, fragmented, or dependent on unnecessary custom build work.

Stablecoin Factory matters because it reduces that friction and gives teams a practical starting point for simple issuance through a more accessible and usable infrastructure model. It creates a more realistic entry point into stablecoin deployment without forcing teams to begin with full enterprise complexity.

Core value

The core value of Stablecoin Factory is low-friction stablecoin deployment.

It gives teams a faster, more accessible way to launch a simple stablecoin and start working with the infrastructure in practice without beginning with the full institutional operating layer.

Short description

Stablecoin Factory is an AI-native self-serve infrastructure product for launching a simple stablecoin with lower friction and a faster path from concept to live deployment.

Digital Cash

Overview

Digital Cash is enterprise infrastructure for already-licensed institutions that want to issue and operate their own digital cash programme through a full operational model.

It is designed for institutions that need more than simple issuance. It provides the infrastructure layer behind institution-run digital cash, including settlement, on and off ramps, multi-currency issuance, treasury functionality, and asset movement across environments. The purpose is not simply to launch a token. The purpose is to establish a credible route into live digital cash

operations with the structure, control, and operational depth required in real financial environments.

Digital Cash should be understood as infrastructure, not as the visible issuer, operator, or customer-facing financial institution. We do not issue. The customer does, under its own licence. Because the licence sits with the customer, the product can be sold globally where the customer's own permissions allow.

Who it is for

Digital Cash is built for banks running tokenised deposits, banks managing intra-bank settlement, clusters of fintechs clearing between themselves, conglomerates with their own licences, and other already-licensed financial institutions that want to launch and operate their own digital cash model.

It is especially relevant for institutions that need a stronger operating layer behind issuance, including settlement, treasury, interoperability, and value movement across real financial environments.

How it is sold

Digital Cash is sold as the full institution-ready infrastructure layer behind a customer-issued digital cash programme.

The commercial message is not that we become the issuer. The message is that the institution can launch and operate its own programme on top of infrastructure that is more structured, easier to deploy, and more operationally credible than building the full stack internally. It is sold through enterprise contracts and modular capabilities based on the customer's operational needs. We only sell the full enterprise version to already-licensed institutions.

Why it matters

Institutional adoption depends on more than the ability to issue an asset. It depends on whether digital cash can function inside real operating environments with settlement, ramps, treasury, interoperability, and value movement built into the model.

Many institutions do not need a token demo. They need a live operating system. Digital Cash matters because it provides a clearer route from issuance to real operation through infrastructure built for institutional reality rather than technical experimentation.

Core value

The core value of Digital Cash is full institutional operating infrastructure.

It gives already-licensed institutions a structured path from issuance to live operation with stronger control, lower infrastructure burden, and a clearer route into real deployment.

Short description

Digital Cash is enterprise infrastructure for already-licensed institutions that want to issue and operate their own digital cash programme with settlement, ramps, treasury, multi-currency issuance, and stronger operational control.

Closing Positioning

Together, the suite covers three connected needs.

Pay by Bank provides the payment rail for direct bank payments in the UK, with a clear commercial path under permission already in force.

Stablecoin Factory provides the low-friction entry point for teams that want to launch a simple stablecoin through a self-serve deployment model.

Digital Cash provides the full institutional infrastructure layer for already-licensed organisations that want to issue and operate digital cash in real financial environments.

This makes the product architecture clearer.

It is not one product trying to speak to everyone. It is one focused suite designed to make money usable across payments, stablecoin deployment, and institutional financial infrastructure.
